RESEARCH OVERVIEW / VERSION 1.0.0

Autonomous Questioning Structural Intelligence (AQSI)

Question Discovery · Multi-Granularity Influence Scoring · Structural Relay · Research Governance

Key idea

AQSI investigates how an AI research system might move beyond answering supplied questions to discovering, evaluating, selecting, exploring, and relaying research questions. The goal is not more questions, but better evidence-aware inquiry and cumulative research value.

Proposed research architecture

01 Discover	Gaps, anomalies, unresolved residuals, associations, and prior inquiries.
02 Represent	Typed Question Units, UTN alignment, multi-granularity factors, and provenance.
03 Evaluate	Directional influence, historical question intelligence, and portfolio selection.
04 Explore	Explicit exploration contracts, evidence, counterevidence, and authorization.
05 Relay & evolve	Question-to-question relay, collective learning, and controlled meta-questioning.

What is in this release

10 core papers · 4 specifications · 3 illustrative cases · 3 extensions · architectural figures and a validation roadmap. The research covers historical question scoring, cross-domain transfer, strategic control planes, and proposed recursive structural improvement.

Scientific status & boundaries

This is a theory-first research framework, not a validated autonomous science system. Proposed algorithms, improvements, and recursive-evolution hypotheses require controlled experiments and independent replication. Question selection does not confer execution authority; strategic goals and permissions remain subject to human governance.
